

Screen Name: ALL Member Digital Wallet

- **Target User:** Customer
- **Primary Database View:** member_purchase_summary_view
- **How it Works:** When a customer opens their app, the interface queries the database using their unique member ID or phone number. Instead of running a complex, slow query to calculate their total history, the front-end pulls directly from member_purchase_summary_view. This view instantly gathers their phone number, active points balance, total visits, and lifetime spend.
- **Data Integrity Rules (Constraints):**

chk_positive_points_balance: The database prevents any transaction from deducting more points than a customer actually has. If an error occurs, the database blocks it, and the app UI safely displays a minimum of 0 points rather than a negative number.

- **Sample View Output (Using Seed Data):**

member_id	phone_number	points_balance	total_transactions	total_spent

1	+66-81-123-450 1	150	1	39.00

PAYMENT METHOD

Digital Wallet

Card Cash **Wallet**

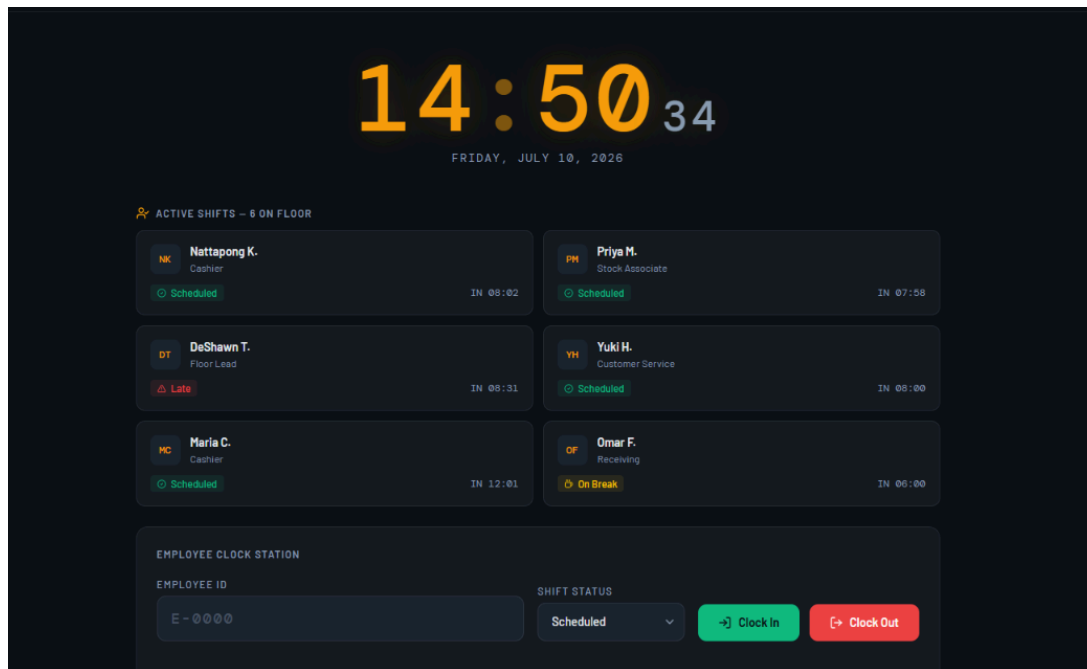

Complete Checkout
₱315.65

- **Target User:** Store Cashier
- **Primary Database Tables:** sales_transactions and transaction_items
- **How it Works:** When a customer brings items to the register, the cashier scans them, creating list items in the UI. When the cashier clicks "Complete Checkout," the front-end executes two SQL INSERT statements to record the transaction details and the specific items (including expiration dates) sold.
- **Data Integrity Rules (Constraints):**
 1. **chk_valid_payment_method:** The "Payment Method" drop-down in the UI is strictly limited to: *CASH*, *CREDIT_CARD*, *DEBIT_CARD*, *TRUE_MONEY*, or *SCAN*. Any other input is blocked at the database level.
 2. **chk_positive_quantity:** The quantity of scanned items must be greater than zero, preventing checkout bugs like scanning "-1" of a product.
- **Behind-the-Scenes Automation (Database Triggers):** The moment the transaction is recorded, the database instantly runs three critical operations on its own:
 1. **trg_update_stock:** Automatically subtracts the sold items from store_inventory.
 2. **trg_all_member_points:** If a member's phone number was entered, this trigger automatically divides the total purchase amount by 25, drops the decimal (using FLOOR), and adds those points to their balance.
 3. **trg_stock_reorder:** If the item's stock drops below 10, the database immediately places a wholesale order to the supplier with a status of 'ORDER SENT'.
- **Sample Database Output (Using Seed Data):**

transacti on_id	store _id	membe r_id	employe e_id	total_am ount	transaction _date	payment_m ethod
1	1	1	4	39.00	2026-07-08 08:30:00+07	CASH

transaction_id	product_id	expiration_date	quantity	unit_price
1	1	2026-07-11	1	39.00

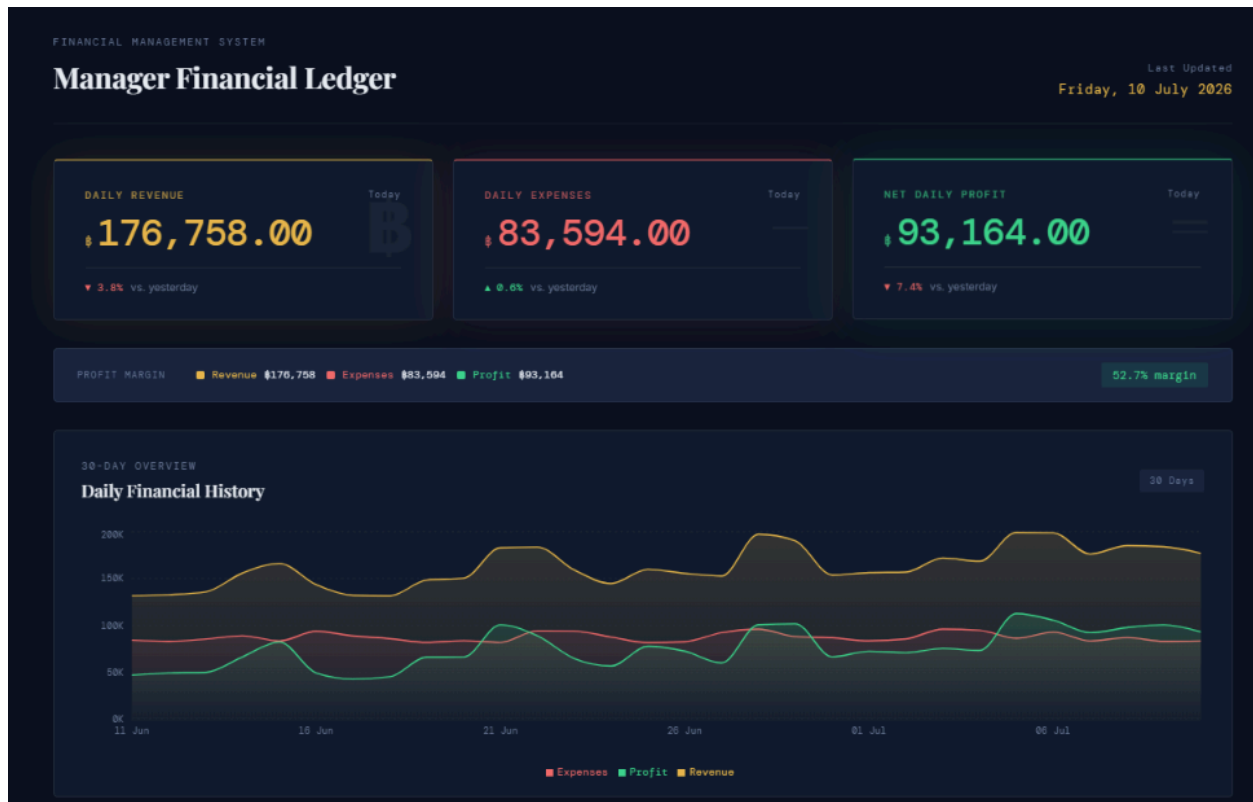

Screen Name: Employee Shift Punch Kiosk

- **Target User:** Store Employees and Branch Manager
- **Primary Database Objects:** worker_shifts (Table) and active_staff_view (View)
- **How it Works:** Employees use this back-room tablet to track their working hours. When an employee logs in, the screen displays the active_staff_view, instantly showing the manager who is currently on the floor (where clock_in is recorded but clock_out is NULL).
- **Data Integrity Rules (Constraints):**
 - **chk_valid_shift_status:** The system strictly limits a shift's status to specific states: *SCHEDULED*, *ACTIVE*, *COMPLETED*, *ABSENT*, or *CANCELED*. This prevents managers from typing in invalid or custom status codes.
 - **chk_valid_shift_timeline:** The database provides foolproof time-theft and error protection. If a user accidentally attempts to submit a "Clock Out" time that occurred *before* their "Clock In" time, the PostgreSQL database outright rejects the insert.
- **Sample View Output (Using Seed Data via active_staff_view):**

store_id	employee_id	employee_name	role_type	clock_in
1	19	Paveena Yim	SECURITY	2026-07-11 07:00:00

Screen Name: Manager Financial Ledger

- **Target User:** Store Manager / Franchise Owner
- **Primary Database View:** manager_daily_net_profit
- **How it Works:** This dashboard compiles three distinct database views to give managers a real-time, high-level summary of store performance. Instead of making the frontend calculate complex math, it directly queries manager_daily_net_profit.
 - In the background, manager_daily_financials aggregates daily store transactions.
 - Meanwhile, manager_daily_expenses sums up total store operational costs (such as utilities, logistics, or waste).
 - Finally, manager_daily_net_profit automatically joins these two views together on their respective dates to compute the net balance.
- **Data Integrity Rules (Constraints):**
 - **chk_valid_expense_type:** Enforces strict categorization of business costs, only allowing inputs like *RENT*, *UTILITIES*, *SALARIES*, *INVENTORY_RESTOCK*, *MAINTENANCE*, *MARKETING*, or *MISCELLANEOUS*.
 - **chk_positive_amount:** Prevents human error by ensuring any logged utility or operational expense amount is positive.

- **chk_positive_total_amount:** Guarantees that sales totals cannot accidentally be processed as negative values.
- **Sample View Output (Using Seed Data via manager_daily_net_profit):**

day_net_profit	net_profit_date
-61781.00	2026-07-08

- **Target User:** Regional Corporate Auditor / Franchise Owner
- **Primary Database Tables:** price_history_audit, expenses_audit, and transaction_audit
- **How it Works:** This secure interface serves as a read-only logging view for corporate security personnel. It monitors any unauthorized modifications or internal tampering. The frontend never has to calculate or manually push data to these tables; the logging happens entirely at the database layer.
- **Behind-the-Scenes Automation (Database Triggers):**
Whenever an internal record is updated or deleted, PostgreSQL silently intercepts the action and executes the corresponding auditing logic:

- **trg_price_audit**: Automatically tracks if anyone updates a product's price, firing `fn_price_audit()` to capture the `old_price`, `new_price`, the database username (`current_user`), and the exact microsecond timestamp.
- **trg_deleted_product_audit**: If a product row is purged from the catalog, this trigger immediately backs up the deleted record id into the archive table.
- **trg_expenses_audit / trg_transaction_audit**: Captures any updates made to financial expense entries or sales invoice values respectively.
- **Sample Database Audit Outputs (From Audit Schema Data):**

price_history_audit Table Entry:

audit_id	product_id	old_price	new_price	changed_by	change_time	change_date
1	1	25.00	29.50	postgres_admin	2026-07-10 15:13:48+07	2026-07-10

deleted_products_audit Table Entry:

audit_id	old_product_id	changed_by	change_time	change_date
1	99	cashier_user01	2026-07-10 11:24:02+07	2026-07-10
